Re: Application of **Raymond Anthony KEEFE**

### FAULT LOCATION DEVICE AND METHOD

Assignee: **AEGIS PTY., LTD.**

Our Ref: **Q68473**

Dear Sir:

The following documents and fees are submitted herewith in connection with the above application for the purpose of entering the National stage under 35 U.S.C. § 371 and in accordance with Chapter II of the Patent Cooperation Treaty:

- ☒ a Form PTO-1449 listing the ISR references, and a complete copy of each reference.
- ☒ a Preliminary Amendment

The executed Declaration and Power of Attorney, and executed Assignment with PTO form 1595 will be submitted at a later date.

It is assumed that copies of the International Application as filed, the International Search Report along with complete copies of the references cited therein, copies of the priority documents, the International Preliminary Examination Report, and any Articles 19 and 34 amendments as required by § 371(c) will be supplied directly by the International Bureau, but if further copies are needed, the undersigned can easily provide them upon request.

Applicant claims benefit of small entity status in accordance with 37 C.F.R. § 1.27.

**Please see attached preliminary amendment before calculating Government filing fee.**

The Government filing fee is calculated as follows: **(Small Entity Fees Apply)**

Total claims	<u>10</u>	-	20	=	<u>0</u>	x	\$9.00	=	<u>\$0.00</u>
Independent claims	<u>2</u>	-	3	=	<u>0</u>	x	\$42.00	=	<u>\$0.00</u>
Base Fee									<u>\$445.00</u>
<b>TOTAL FEE</b>									<u><b>\$445.00</b></u>

A check for the statutory filing fee of \$445.00 is attached. You are also directed and authorized to charge or credit any difference or overpayment to Deposit Account No. 19-4880. The Commissioner is hereby authorized to charge any fees under 37 C.F.R. §§ 1.16, 1.17 and

Sughrue

SUGHRUE MION, PLLC

Entering National Stage of PCT/AU00/00964  
Attorney Docket Q68473

1.492 which may be required during the entire pendency of the application to Deposit Account No. 19-4880. A duplicate copy of this transmittal letter is attached.

Priority is claimed from:

<u>Country</u>	<u>Application No</u>	<u>Filing Date</u>
Australia	PQ2157/99	August 11, 1999

### BRIEF DESCRIPTION OF THE DRAWINGS

Page 7, after the description of figure 16 insert the heading

**DETAILED DESCRIPTION OF THE INVENTION**

**IN THE CLAIMS:**

Delete the heading "CLAIMS:-" and insert the heading

**WHAT IS CLAIMED IS:**

Please enter the following amended claims:

3. (Amended) A device as claimed in claim 1, incorporating means for detecting and removing signal artifacts due to switching transients or other external interference.
4. (Amended) A device as claimed in claim 1, having means for determining a confidence indication, indicating a degree of reliability of said result.
7. (Amended) A device as claimed in claim 5, wherein said selected criteria is or includes the signal-to-noise ratio of the result signal and/or said signal components.
8. (Amended) The device as claimed in claim 5, wherein said selected criteria is or includes the absolute signal strength of the result signal, and/or said signal components.

**IN THE ABSTRACT:**

Please add the required proper Abstract of the Disclosure found on the attached unnumbered sheet.

**REMARKS**

The application has been amended to delete the multiple dependencies therein, to provide appropriate headings for the various sections of the specification, and to add the proper required Abstract. Entry and consideration of this Amendment and an early and favorable action on the merits is respectfully requested.

Respectfully submitted,

Robert V. Sloan

## **ABSTRACT**

Device (32) for determining location of a fault in an underground cable causing an earth leakage path from an internal conductor to each at the location of the fault, such that when signal is applied to the conductor, earth leakage signal flows between the earth and conductor at the location of the fault. A multi-frequency signal is applied to the cable, this having at least two frequency components. Probe means (24a, 24b) is positionable to receive the earth leakage signal. A processor (50) rectifies a first component of the earth leakage signal, corresponding to one frequency component of said applied signal, multiplies the rectified first component of the earth leakage signal with a second component of the earth linkage signal, corresponding to another frequency component of the applied signal, and from the result of that multiplication indicates the direction from the device to the fault.

### FAULT LOCATION DEVICE AND METHOD

This invention relates to a fault location device and method, useful for determining the position of a fault in a cable.

5

Buried underground cables and pipes (often referred to as "services") sometimes develop faults and are not always clearly marked on plans, especially if they were not recently installed.

Precise fault location is desirable in the interests of reducing the amount of digging  
10 required to repair the cable. Underground cables can develop a number of different faults. Some examples are:

15

- open circuit;
- short circuit to another conductor;
- short circuit to the shield; and
- short circuit to the ground, also known as a sheath fault because the cable sheath  
has been breached.

A fault of primary interest is the sheath fault. One common method of detecting the location of this is to use a ground probe to search for maximum signal strength. This is effective  
20 because the ground is a volume conductor and the fault current is denser near the fault than it is as one moves further away. The maximum current point will be nearest the fault. One drawback of this method is that it is not possible to tell the direction to the fault and one must hunt to find whether one is moving closer to the fault or further from it. It is possible to address this limitation by various methods.

25

One method employs a large DC voltage to produce a deflection on a DC voltmeter. The direction of the deflection shows the direction to the fault, as the current flow is always away from the fault. The disadvantages of this method are that there are often DC current offsets in the soil which can give false readings and most cable connected equipment may not be tolerant  
30 of high DC voltage levels.

- 2 -

Another method is to use a very large voltage pulse to produce a deflection on a meter. The direction of the deflection shows the direction to the fault. The disadvantages of this method are that it is unreliable in wet soil, and the voltage pulse can damage the cable insulation or connected devices. The advantage over the DC voltage method is that it reduces problems  
5 due to local DC or very low frequency AC currents in the soil.

A further method involves adding a higher frequency carrier signal which is picked up by an antenna. This is processed and compared to the signal in the ground to determine the polarity of the signal in the ground. This method has the advantage that the ground signal can  
10 be a continuous AC signal. The drawback is that one must keep the receiving device locked to the cable frequency, and higher frequencies have a lower range.

Another method uses multiple harmonically related frequencies simultaneously to try and calculate the direction to the fault. The phase relationships of the signals are compared and  
15 the sign of the deviation between them is used to determine the direction to the fault. The sign of the phase deviation is equal to the polarity of the signal and hence the direction can be calculated. The advantages of this method are that it lessens the problems with DC signals, and also overcomes the need to keep the receiver locked to an external signal on the cable. The disadvantage is that errors in signal phase caused by noise and mains switching transients can  
20 produce incorrect results, effectively pointing the user of the device in the wrong direction.

A method of sheath fault location using a transmitter and a ground probe based receiver illustrated in Figure 1.

25 A signal is placed on the cable 14 at a convenient access point by use of a generator 20. The return path for the signal is ground. The actual conductor used is the one with the sheath fault on it, otherwise there would be no return current. The fault is represented by an impedance 22 to ground and located at location 23 along the cable. In practice, the ground return path is complex and depends on the type of soil, moisture content, depth of cable and the presence of  
30 other buried conductors such as metal water pipes.

- 3 -

A ground probe 24, represented as a volt meter, is used to measure the voltage potential in the ground to determine the direction from the ground probe to the fault. This has two ground probe elements 24a, 24b which are positioned in spaced relationship in the ground, the probe if necessary being moved to various successive ground locations at which the probes are entered  
5 into the ground, and meter readings taken at the voltmeter.

Near to the fault, the ground currents branch out from the fault. Because of this, the ground probe can correctly identify the direction to the fault from either side of the fault. Directly over the fault, there is no signal at all and it is by determining the location of the probe  
10 at which this result ensues that the location 23 of the fault is determined. This is illustrated in Figure 2 where the currents branching out from cable 14 at the fault are illustrated diagrammatically by arrows 26, and the polarities of detected signal at the voltmeter when positioned along the length of the cable, but to opposite sides of the fault is shown as being relatively reversed. There is no detected signal when the voltmeter is positioned adjacent the  
15 fault, and this is how the fault is located.

To reduce losses due to cable capacitance, lower frequencies are preferred. But frequencies in the normal operating range of the cable may cause cross talk and interference to other cables. As a result, frequencies below 300Hz or above 3.4KHz may be preferred.  
20 Frequencies below 300Hz are however close to the harmonics and fundamentals of power frequency transmission equipment. As a result, signals well below 50/60Hz may be most preferable.

There are three basic methods that might be used to show the direction to fault:

- 25
- DC shift;
  - cable carrier and/or locked carrier reference; and
  - phase deviation.

The DC shift method involves either placing a large DC voltage on the cable or using  
30 a large pseudo impulse. The latter is preferable because it is less susceptible to local DC and low frequency AC currents, but both methods suffer from limited range in the wet and the

- 4 -

possibility of damaging the cable.

The method cable carrier and/or locked carrier reference involves locking an on-board reference to the transmitter. This can be most easily achieved by sending a carrier signal down the same cable and picking it up with an antenna. Alternatively, a radio based carrier system could be used. Another method is to lock the receiver to the transmitter and hold the lock using a very low drift oscillator. In practice, a low drift oscillator locked to a cable borne signal may be more easily achieved. The disadvantage is that cable borne signal must be a high enough frequency to be readily picked up by a compact antenna and this normally brings it into or above the voice band. Signals in the voice band are not preferred by telecommunications carriers and higher frequencies are harder to keep phase aligned due to capacitive effects in the cable.

The phase deviation method involves using more than one frequency and measuring the direction of phase deviation between the two signals. If the direction of deviation is one polarity, then the fault lies in one direction, otherwise it lies in the other. These methods suffer from the fact that phase distortion or noise can cause erroneous results, even reversing the direction. Lower frequencies are preferred to improve range and reduce phase distortion due to capacitive effects, but because of the close proximity to mains power frequencies and their harmonics, substantial filtering is required. Filters are difficult to make phase shift free, and high Q band pass filters can ring in the presence of noise and switching transients, giving rise to false detections and incorrect direction results. At the very least, careful phase alignment is required.

In all of the above cases, it is difficult to provide high confidence that the user will correctly interpret the results and know when to ignore spurious readings.

The DC shift method involving high voltage pseudo impulses requires the operator to ignore slowly drifting meter movements, and to recognise a characteristic flicker due to the voltage spike. Audible feedback from the transmitter also helps for nearby faults. Unfortunately once the signal level drops, it is difficult for the operator to distinguish the random noise from the signal which is then likely to be minuscule.

- 5 -

The cable carrier systems and phase deviation systems have a similar difficulty. Once the signal level falls, the meter indicator can move sporadically in either direction, and it is hard for the user to objectively interpret the result.

5 Some systems attempt to also give the user an idea of the signal level, but this can also be misleading. A weak signal in a quiet area may be much more usable than a strong signal in a very noisy area such as near a mains power substation or railway line with track circuits energised to detect passing trains. Systems which ignore signals once the level falls sacrifice range.

10

The invention provides a device for determining location of a fault in an underground cable causing an earth leakage path from an internal conductor to earth at the location of the fault whereby, when signal is applied to the conductor, earth leakage signal flows between the earth and conductor at the location of the fault, wherein the applied signal is a multi-frequency  
15 signal having at least two frequency components, the device having probe means positionable to receive the earth leakage signal, and means for rectifying a first component of the earth leakage signal corresponding to one said frequency component of said applied signal, multiplying the rectified first component of the earth leakage signal with a second earth leakage signal corresponding to another frequency component of the applied signal and, from the result  
20 of said multiplication, determining the direction from the device to the fault.

Preferably, the device incorporates means for detecting and removing artifacts due to external interference such as switching transients.

25 Preferably, the device incorporates means for determining a confidence indication, indicating a degree of reliability of said result. The last-mentioned means may operate to determine said confidence indication by applying selected criteria to said result, such as the ratio between maximum positive and negative excursions thereof, and/or the signal-to-noise ratio of the detected signal and/or the absolute signal strength of the detected signal, and/or said signal  
30 components.

- 6 -

The invention also provides a method for determining location of a fault in an underground cable, wherein signal is applied to the cable to cause generation of an earth leakage signal from an internal conductor of the cable to earth, at the location of the fault, the applied signal being a multi-frequency signal having at least two frequency components, receiving the  
5 earth leakage signal, and rectifying a first component of the earth leakage signal corresponding to one frequency component of said applied signal, multiplying the rectified first component of the earth leakage signal with a second frequency component of the earth leakage signal corresponding to another said frequency component of the applied signal and, from the result of said multiplication, determining the direction from the device to the fault.

10

Some or all of signal processing may be effected digitally, under control of suitable software. The invention also provides a method for determining location of a fault in an underground cable, wherein signal is applied to the cable to cause generation of an earth leakage signal from an internal conductor of the cable to earth, at the location of the fault, the applied  
15 signal being a multi-frequency signal having at least two frequency components, receiving the earth leakage signal, and rectifying a first component of the earth leakage signal corresponding to one frequency component of said applied signal and multiplying the rectified first component of the earth leakage signal with a second frequency component of the earth leakage signal corresponding to another said frequency component of the applied signal, such that the result  
20 of said multiplying then represents the direction from the device to the fault. The multiplication may be effected as an array multiplication of sets of time-spaced samples of the first and second components of the earth leakage signal.

The invention is further described, by way of example only, with reference to the  
25 accompanying drawings, in which:

Figures 1 and 2 illustrate general principles of fault location in a cable;

Figure 3 is a waveform diagram showing waveforms applied to a cable for fault location  
30 detection in accordance with a fault location device constructed in accordance with the invention;

- 7 -

Figure 4 is a diagram of a fault location device constructed in accordance with the invention;

Figure 5 is a waveform diagram illustrating signal manipulations effected in accordance with the invention;

Figures 6, 7 and 8 are diagrams illustrating operation of the fault locating device in accordance with the invention; and

Figures 9 to 12 are flow charts describing software manipulation effected in operation of a fault locating device constructed in accordance with the invention;

Figure 13 illustrates steps in computing confidence results in a fault locating device of the invention;

Figure 14 is a front view of a fault location device of the invention;

Figure 15 is a side view of the fault location device of Figure 14; and Figure 16 is a plan view of the fault location device of Figure 14.

The exemplary embodiment of the invention to be described uses a transmitter which in use is connected to a cable and applies to it a multi-frequency signal. In this exemplary embodiment, two frequency components are applied, having frequencies of 8 Hz and 16 Hz respectively.

Figure 3 shows the waveform produced at the transmitter and its 8Hz and 16Hz components. Here, the amplitude of the final composite 8Hz+16Hz waveform is kept to below 150V Peak to Ground which will not harm normal telephony cable insulation nor most connected devices. The waveform is a simple mix of two frequencies. A factor of 2 is used for the two frequencies. Other factors could be used but a more complex function than taking the absolute value of the lower frequency would be required and the repetition interval would

- 8 -

increase which would slow down the measurement rate. Also, if higher factors are used then it is much harder to filter out the noise and interference signals, especially if you are operating below the normal mains power frequencies. If ratios below 2 are used, eg. 3:2, then the filtering problems are avoided but more complex functions and longer repetition intervals are again  
5 required. Choice may best be based on a balance between filtering, ambient signals and the time it takes to collect the sample. At 8Hz it takes 125msecs for a full wavelength, at 4Hz it takes 250msecs and at 0.1Hz excessively long processing times may result.

The form of the transmitter waveform is preferably relatively simple, and largely non-  
10 critical, as described. This is advantageous, because the signal is transmitted through ground which is a noisy and unpredictable medium. Special features may become distorted and a complex spectral or phase based pattern may be rendered unrecognisable, especially as the distance from the fault to the ground probe increases.

15 Figure 4 shows a ground probe 32 useful in practising the invention. This has a differential amplifier 34, used to amplify the voltage difference between ground probe elements 36. Fifth order low pass and high pass filters 38, 40 are used to remove out of band noise. These are set at 24Hz and 4Hz respectively. A notch filter 42 is also used to remove mains power primary frequencies, at for example either 50Hz or 60Hz. The resulting signal is  
20 amplified at amplifier 44 and fed through two band pass filters 46, 48 to isolate the 8Hz and 16Hz signal components. A delay equaliser (not shown) is used to compensate for phase shift between the signals as a result of the processing.

Once the 8Hz and 16Hz signals are acquired, they are processed by a processor 50.  
25

In order to obtain polarity information from the so extracted waveforms without using phase deviation and its inherent problems with noise immunity, the 8Hz signal is first rectified. Next it is array multiplied with the 16Hz signal.

30 The multiplication is element-by-element in the following manner:

- 9 -

$$[a_1, a_2, a_3, a_4 \dots] * [b_1, b_2, b_3, b_4 \dots] = [a_1 * b_1, a_2 * b_2, a_3 * b_3, a_4 * b_4 \dots]$$

where  $a_n$  and  $b_n$  are respective time spaced samples of the rectified 8Hz signal and the 16Hz signal.

5

The resulting signal shows a reproducible characteristic with the mean offset being in the direction of the 16Hz signal peak which is closest to the 8Hz signal peak. This characteristic may be stable with nearly 90 degrees of phase shift in the 16Hz signal. This is a substantial improvement over the phase deviation methods. Figure 5 illustrates these manipulations.

10

It is noted that there is an obvious ratio between the maximum negative excursion and the maximum positive excursion. This is at around 1:4. There is also a natural ratio between the mean and the maximum positive excursion. This is around 1:6. By applying these metrics to the acquired signal it is possible to deduce the likelihood that the signal has only good

15 components.

Also, if a switching transient does occur, there will be expected to be a substantial discrepancy in the metrics. If all signals that exceed the peak to mean ratio are clipped, and the metric re-run, then the influence of the positive peak will be expected to be reduced and no longer cause an excessive contribution to the mean calculation.

20

Figure 6 shows the above-mentioned rectified and array multiplied signal in the case where this includes a large interfering peak.

25

The mean in this case is very slightly negative, although the mean for just the signal components that are part of the transmitted waveform would be expected to be positive. Figure 7 shows the signal after the metric has been run and the peak excursions clipped. As can be seen, the mean is now positive, and the effect of the interference has been overcome.

30

It is also possible to use the metric to eliminate results that are so heavily distorted that they cannot be successfully corrected. This lessens the problem of giving the operator a

- 10 -

misleading result which the operator must otherwise recognise and ignore. The unit may do that for the operator, and at least substantially avoid providing spurious data.

Because the mean of the array multiplied signal is known, both before and after the clipping, the ratio of these means can be used to gain confidence in the direction indication. If the ratio is close to one, then the original signal conformed fairly well to the target metric and is likely to be good. If the ratio is high, then confidence is reduced as the original signal did not fit the profile very well.

10 In addition, the ratio of the peak to the mean is also well defined. If this is within allowed limits before and after the clipping then confidence is high. If the ratio was outside the limits before clipping but came back into line after clipping, then confidence is less. If the ratio is poor for both cases then confidence is low.

15 For example, start with confidence = 100%.

1. If the peak to mean ratio before clipping was more than 20, and the target was 6, then reduce confidence by 50%, otherwise if the ratio was 10 then reduce confidence by 25%.

2. Now clip the signal. If the new peak on mean ratio is more than 20, then half the confidence, otherwise if it is more than 10, then reduce confidence to  $\frac{3}{4}$  of the previous amount.

20 3. Now divide the peak on mean ratio before clipping by the peak on mean ratio after clipping. If this ratio is more than 3 then reduce confidence by  $\frac{1}{2}$ , else if it is greater than 2, then reduce confidence to  $\frac{3}{4}$  of the previous value.

At the end of this, a final confidence interval is reached. For a good clean signal, confidence will be 100%. This is as expected. If the signal was clean enough after clipping but a bit dirty beforehand, confidence will be 75%, and so on. This process can be extended to any number of steps depending on the complexity of the metric. The exemplary thresholds given here have been found satisfactory for the waveform and metric used as an example of the method. Once the confidence falls to a low enough level, ie  $< 33\%$ , then declaring results may be stopped as the results are almost certainly unreliable.

- 11 -

Although a specific implementation is described here in order to properly explain the invention, other enhancements are also possible.

The transmitted power can be increased without increasing the peak voltage excursion of the waveform by altering the phase relationships between the waveforms. Figure 8 illustrates this. As can be seen, the peak excursion of the second waveform is symmetrical at about +/- 1.8, whereas the initial waveform has a peak positive excursion of 2. Both have a DC average of zero. The receiver must realign the phases again to ensure the metrics still work but this is simple to do.

10

The example implementation here employs a mixture of analog and digital processing. The selection of which part of the process is done in which way is a matter of design choice. Metrics may be done using analog circuitry, and the filtering could also be done digitally with A/D sampling earlier in the chain. The choice of signal processing method is not critical to the implementation of the improved method for finding the sheath fault location.

15

Although this implementation only uses two frequencies, it is possible to extend the methods used to multiple frequencies and similar metrics across these frequencies in groups of two or more at a time.

20

In addition to measuring basic waveform metrics such as peak to mean ratio, other more complex metrics can be applied, such as least squares fit to a target waveform. The specific choice of metrics is a compromise between ease of computation and likelihood that error detection will be improved by adding the metric. The examples given here have been demonstrated to work satisfactory for a ground based sheath fault locator.

25

Averaging a number of results can further reduce spurious readings. The results can either be averaged when initially collected or else averaged after processing. There are some advantages of post processing averaging as only the better results get included in the average. Use of spurious results should obviously be avoided. The confidence factor can also be used to create a weighted average where the higher confidence results have more bearing on the final

30

result than the lower confidence results.

Figures 9 to 11 are flow charts illustrating software executed steps in an exemplary device constructed in accordance with the invention.

5

Figure 9 shows steps in acquiring data samples of received signal. In samples are acquired at a 256 Hz sample rate, 64 samples being acquired for each overall program execution. This provides 250 mseconds of data or two complete cycles of the 8 Hz waveform.

10 Execution of the data acquisition steps as illustrated in Figure 9 begins by setting a timer for 256 Hz, at step 102, followed by clearing of buffers and a counter at steps 104, 106. Thereafter at step 108, the program awaits the timer, and then reads the 8 Hz and then the 16 Hz signal at steps 110, 112. At the next step, step 114, a counter is incremented by one step and at the following step 116 a determination is made as to whether the count incremented at step  
15 114 has reached 64. If it has not reached 64, steps 108 through to 116 are repeated, this being so repeated until the count reaches 64 after which, at step 118 acquisition is complete.

In the steps illustrated at Figure 10, the 64 data points for each of the 8 and 16 Hz signals as acquired by the process steps shown in Figure 9 are processed. First, at steps 120, 122, 124,  
20 mean, and counter registers peak are cleared. Then, for the first data point acquired, the multiplication of the absolute value of the 8 Hz signal together with the 16 Hz signal is computed, at step 126, to which a mean figure, comprising a previous mean, plus the result of step 126 is computed, this being executed at step 128. After this, at step 130, comparison of the absolute value of the result of step 126 is made with that of a peak value (initially zero) and if  
25 that absolute value is greater than the peak, the peak is, at step 132, updated to reflect the absolute value of the result of step 126. Next, a counter initially set to zero is incremented one step, this being effected at step 134. Then, at step 136, it is determined whether the counter has reached a stored count of 64. If it has not, steps 126 through 136 are repeated, this repeating being effected until the count reaches 64 after which at step 138 there is computed a mean value  
30 representing the mean accumulated by the repeated executions of step 128 divided by 64. After that, at step 140, signal processing is judged complete.

- 13 -

Figure 11 shows program steps for determining a metrics calculation. First, at step 150, the ratio of the peak value to the mean value as computed at steps 132 and 138 is computed. Then, at step 152, an expected peak value is set as the absolute value of the mean computed at step 138 multiplied by six. The program execution of this part of the program is completed after this, at step 154.

Figure 12 illustrates steps in effecting clipping of results according to expected peak result. At step 160, a counter is cleared. Then, at step 162, a comparison is made between the absolute value of the result, as computed at step 126, and an expected peak value. If the absolute value of the result is greater than the expected peak, it is then determined whether the result value is less than zero. If not, the result is set to the expected peak, at step 166; otherwise it is set to the negative of the expected peak at step 172 (described later). If, at step 162, the absolute value of the result is not greater than the expected peak, steps 164 and 166 and 172 are skipped and the program moves to step 168. Program execution precedes from step 166 or step 172 also to step 168, which is to increment the counter. At step 170, it is determined whether the count in the counter has reached 64. If not, program steps 162 and 164 and, if appropriate, one or more of steps 166 or 172, are repeated as before described. Otherwise, results clipping is completed at step 174.

Figure 13 illustrates program steps in computing confidence results, including the steps described in the flow charts of Figures 9, 10, 11 and 12.

Firstly, at steps 180, 182 and 184, the steps illustrated respectively by the flow charts of Figures 9, 10 and 11 are effected. At steps 186, 188 mean #1 and ratio #1 values are set to the mean and ratio value respectively, as computed previously, and results clipping then occurs at step 190, in accordance with the flow diagram of Figure 12. Subsequently, at steps 192, 194 mean #2 and ratio #2 are set to the resultant values of mean and ratio determined at step 190. Then, at step 196, a confidence value is set to 100% and, subsequently, at step 198, a determination is made as to whether the value of ratio #1 is greater than 10. If it is greater, at step 200 it is determined whether ratio #1 exceeds 20. If so, the confidence value is set to confidence \*0.5 at step 202, after which processing proceeds to step 204 later described. In the

- 14 -

event that the result of the comparison of step 198 should be that the ratio #1 is not greater than 10, program execution likewise proceeds at once to step 204. If, at step 200, the ratio #1 is determined as not being greater than 20, then at step 205, the confidence value is set to confidence \*0.75, after which program execution again continues at step 204. At steps 204, 5 206, 208, 212 program steps corresponding to steps 198, 200, 202 and 205 respectively are performed with respect to ratio #2 after which program execution continues at step 210. At step 210, a ratio #3 is computed by dividing the ratio #1 by the ratio #2 value after which program execution continues at step 214. At steps 214, 216, 218 and 222, program steps again corresponding to steps 198, 200, 202, 205 are performed with respect to the ratio #3, after which 10 program execution terminates at step 220, at which confidence calculation is effected.

Figures 14 to 16 show the physical configuration of the fault location device 32. this has a casing 240 with an upper handle 242. Electrical components 246 are housed within the casing. The probes 24a, 24b project in spaced relationship from a framework 248 forming part of casing 15 240. Controls 250 for operating the device 32 are positioned at an upper part of the housing 240.

The described arrangement has been advanced merely by way of explanation and many modifications may be made thereto without departing from the spirit and scope of the invention 20 which includes every novel feature and combination of novel features herein disclosed.

Throughout this specification and the claims which follow, unless the context requires otherwise, the word "comprise", and variations such as "comprises" and "comprising", will be understood to imply the inclusion of a stated integer or step or group of integers or steps but not 25 the exclusion of any other integer or step or group of integers or steps.

The reference to any prior art in this specification is not, and should not be taken as, an acknowledgment or any form of suggestion that that prior art forms part of the common general knowledge in Australia.

## CLAIMS:-

1. A device for determining location of a fault in an underground cable causing an earth leakage path from an internal conductor to earth at the location of the fault whereby, when  
5 signal is applied to the conductor, earth leakage signal flows between the earth and conductor at the location of the fault, wherein the applied signal is a multi-frequency signal having at least two frequency components, the device having probe means positionable to receive the earth leakage signal, and means for rectifying a first component of the earth leakage signal corresponding to one said frequency component of said applied signal, multiplying the rectified  
10 first component of the earth leakage signal with a second component of the earth leakage signal corresponding to another said frequency component of the applied signal and, from the result of said multiplication, determining the direction from the device to the fault.
2. A device as claimed in claim 1, wherein said multiplication is effected as an array  
15 multiplication of sets of time-spaced samples of the first and second components of the earth leakage signal.
3. A device as claimed in claim 1 or claim 2, incorporating means for detecting and removing signal artifacts due to switching transients or other external interference.  
20
4. A device as claimed in any preceding claim, having means for determining a confidence indication, indicating a degree of reliability of said result.
5. A device as claimed in claim 4, wherein said means for determining a confidence  
25 indication operates to determine said confidence indication by applying one or more selected criteria to said result.
6. A device as claimed in claim 5, wherein selected criteria is or includes the ratio between maximum positive or negative excursions of said result, and the means of said result.  
30
7. A device as claimed in claim 5 or claim 6, wherein said selected criteria is or includes

- 16 -

the signal-to-noise ratio of the result signal and/or said signal components.

8. The device as claimed in claim 5, claim 6, or claim 7, wherein said selected criteria is or includes the absolute signal strength of the result signal, and/or said signal components.

5

9. A method for determining location of a fault in an underground cable, wherein signal is applied to the cable to cause generation of an earth leakage signal from an internal conductor of the cable to earth, at the location of the fault, the applied signal being a multi-frequency signal having at least two frequency components, receiving the earth leakage signal, and  
10 rectifying a first component of the earth leakage signal corresponding to one frequency component of said applied signal, multiplying the rectified first component of the earth leakage signal with a second component of the earth leakage signal corresponding to another said frequency component of the applied signal and, from the result of said multiplication, determining the direction from the device to the fault.

15

10. A method as claimed in claim 9, wherein said multiplication is effected as an array multiplication of sets of time-spaced samples of the first and second components of the earth leakage signal.

(54) Title: **FAULT LOCATION DEVICE AND METHOD**

(57) Abstract: Device (32) for determining location of a fault in an underground cable causing an earth leakage path from an internal conductor to earth at the location of the fault, such that when signal is applied to the conductor, earth leakage signal flows between the earth and conductor at the location of the fault. A multi-frequency signal is applied to the cable, this having at least two frequency components. Probe means (24a, 24b) is positionable to receive the earth leakage signal. A processor (50) rectifies a first component of the earth leakage signal, corresponding to one frequency component of said applied signal, multiplies the rectified first component of the earth leakage signal with a second component of the earth leakage signal, corresponding to another frequency component of the applied signal, and from the result of that multiplication, indicates the direction from the device to the fault.

**DECLARATION AND POWER OF ATTORNEY FOR UTILITY OR DESIGN PATENT APPLICATION (37 CFR 1.63)**

As a below named inventor, I hereby declare that: My residence, mailing address, and citizenship are as stated below next to my name. I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

**FAULT LOCATION DEVICE AND METHOD**

the application of which

☐ is attached hereto

OR

☒ was filed on 11 August 2000 as United States Application Number or PCT International Application Number PCT/AU00/00964, (Confirmation No. \_\_\_\_\_), and was amended on \_\_\_\_\_ (if applicable).

I hereby state that I have reviewed and understand the contents of the above identified application, including the claims, as amended by any amendment specifically referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR 1.56, including for continuation-in-part application(s), material information which became available between the filing date of the prior application and the national or PCT international filing date of the continuation-in-part application.

I hereby claim foreign priority benefits under 35 U.S.C. 119(a)-(d) or (f), or 365(b) of any foreign application(s) for patent, inventor's or plant breeder's rights certificate(s), or 365(a) of any PCT international application(s) which designated at least one country other than the United States of America, listed below and have also identified below, by checking the box, any foreign application(s) for patent, inventor's or plant breeder's rights certificate(s), or any PCT international application(s) having a filing date before that of the application on which priority is claimed.

Prior Foreign Application Number(s)	Country	Foreign Filing Date	Priority Claimed	
			Yes	No
<u>PQ2157/99</u>	<u>Australia</u>	<u>11 August 1999</u>	<input checked="" type="checkbox"/>	<input type="checkbox"/>

I hereby claim domestic priority benefits under 35 United States Code §120 of any United States application(s), §119(e) of any United States provisional application(s), or §365(c) of any PCT International application(s) designating the United States, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in a listed prior United States or PCT International application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge my duty to disclose any information material to the patentability of this application as defined in 37 C.F.R. 1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

Prior U.S. or International Application Number(s)	U.S. or International Filing Date	Status
